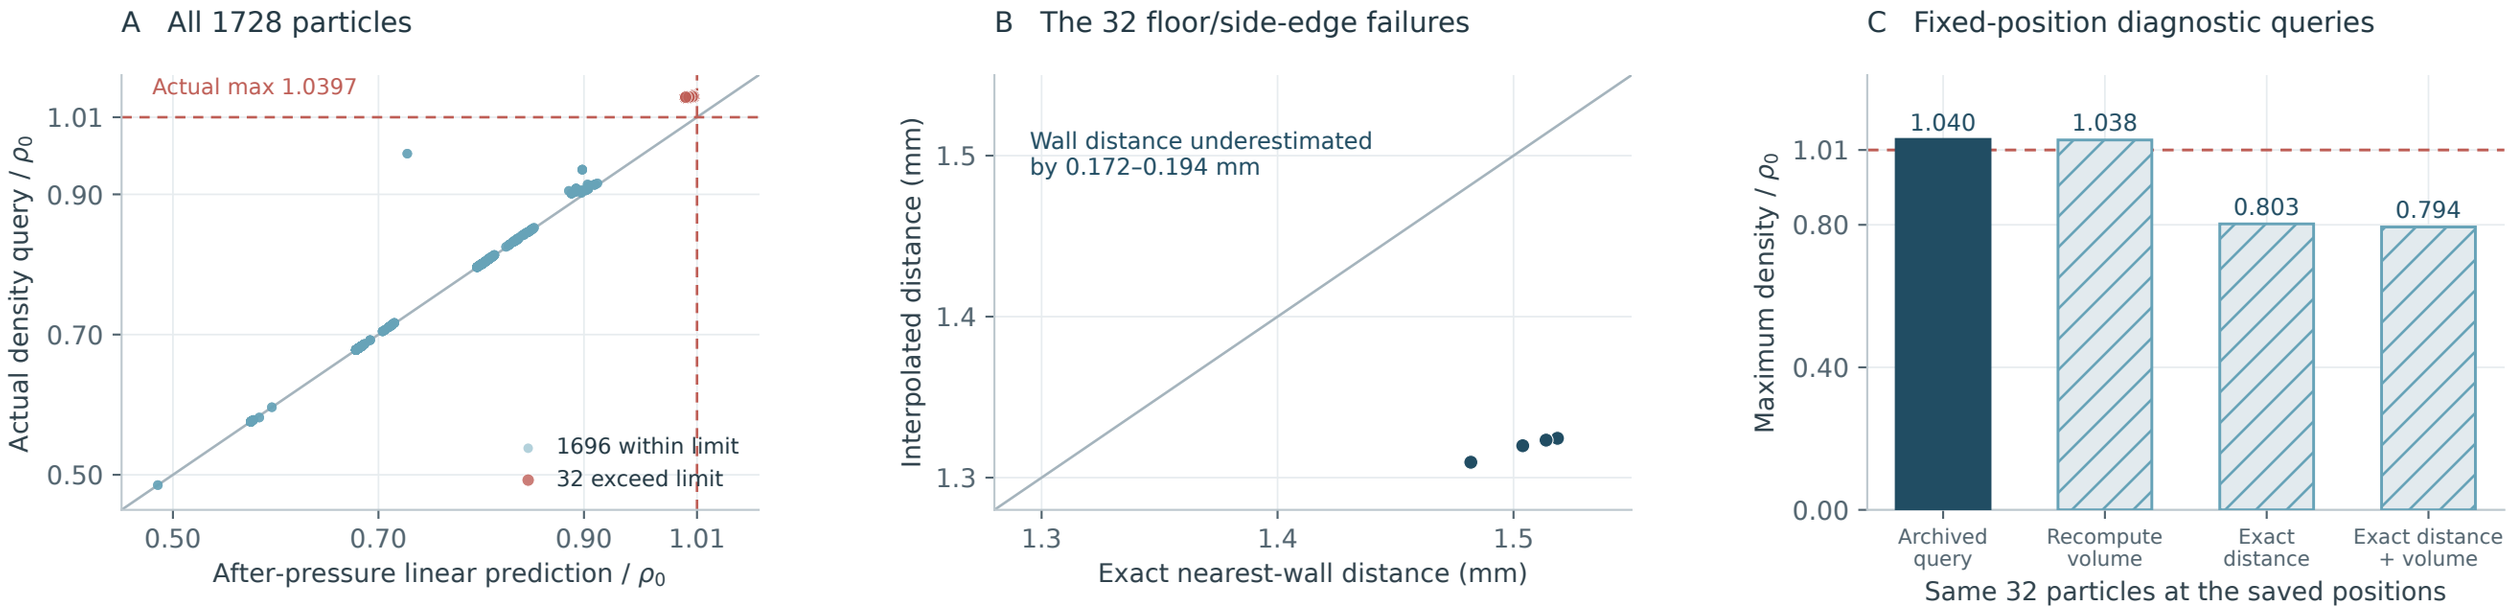
The pressure prediction misses an edge-density overshoot

Archived 1 ms candidate at 18 ms · 1728 particles · the actual trial still fails the 1.01 density ceiling



A: all particles are shown; overlapping points retain their original identities. B: eight failures lie near each of the four floor/side edges.

C: hatched bars change boundary queries only. They do not re-solve pressure, integrate a new trajectory, or demonstrate a physical repair.

Source average-pressure stopping tolerance, linear prediction and actual maximum density are distinct quantities; the failed trial is preserved.
