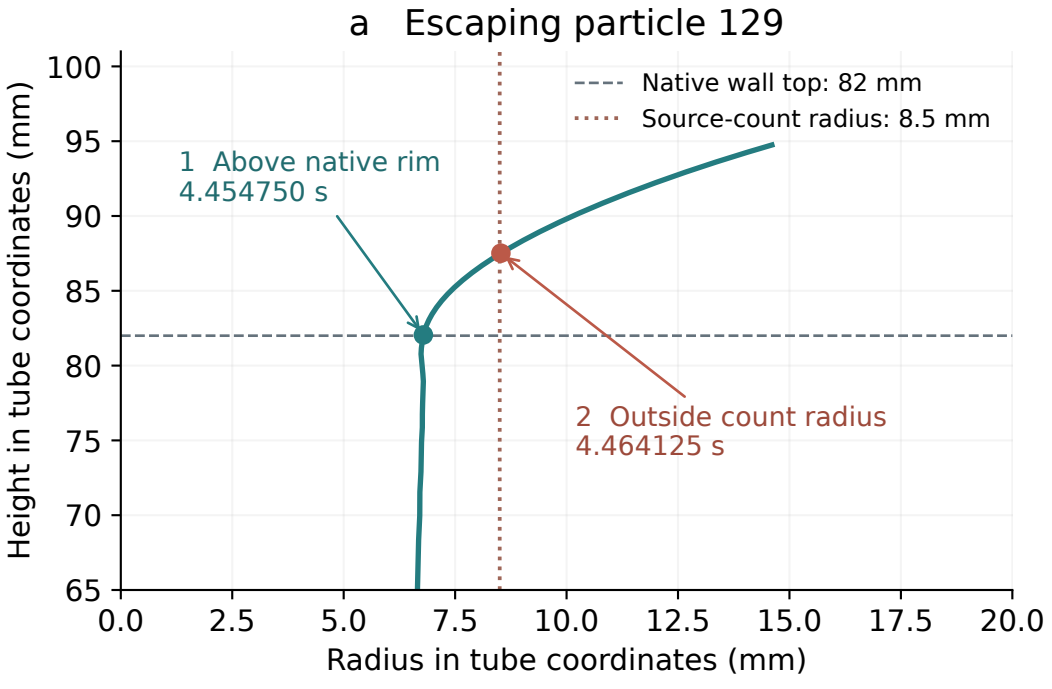
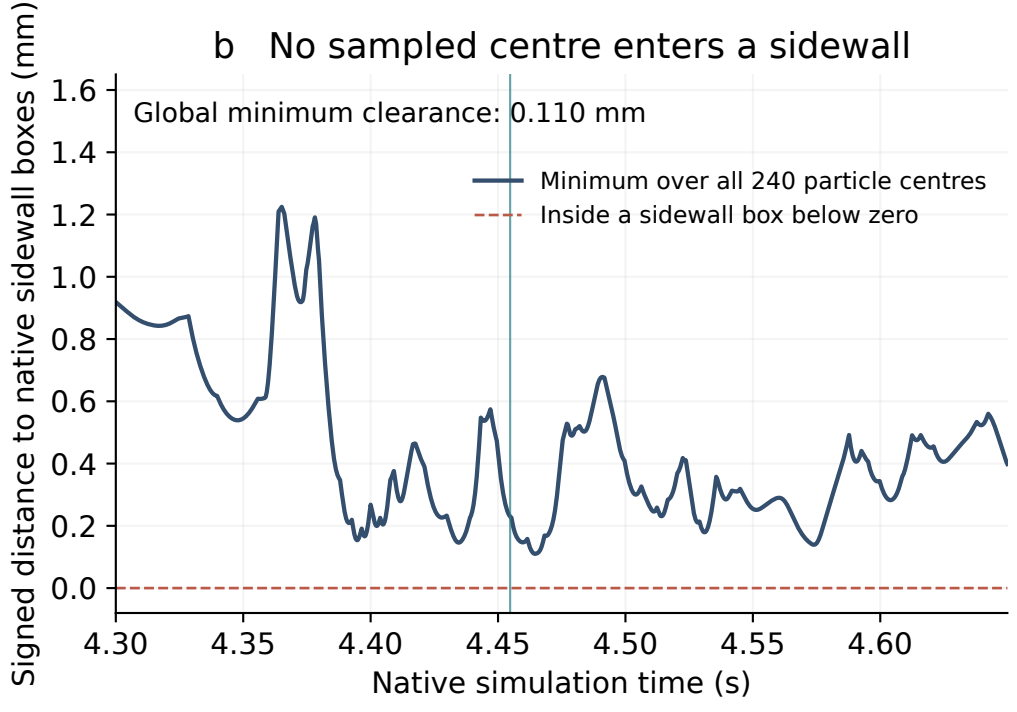
Dual Flexiv: sampled trajectory supports open-top egress

117 shared frames match exactly · 2,800 microsteps at 125 µs · 672,000 particle-centre checks





The original 19 s handoff remains FAIL: this particle subsequently left the frozen workspace.

This diagnosis covers one event, 4.300–4.649875 s. Discrete centre samples do not prove continuous or finite-kernel clearance.

The 8.5 mm radius is a counting boundary; the independent wall-distance test uses the actual 32 native collision boxes.
