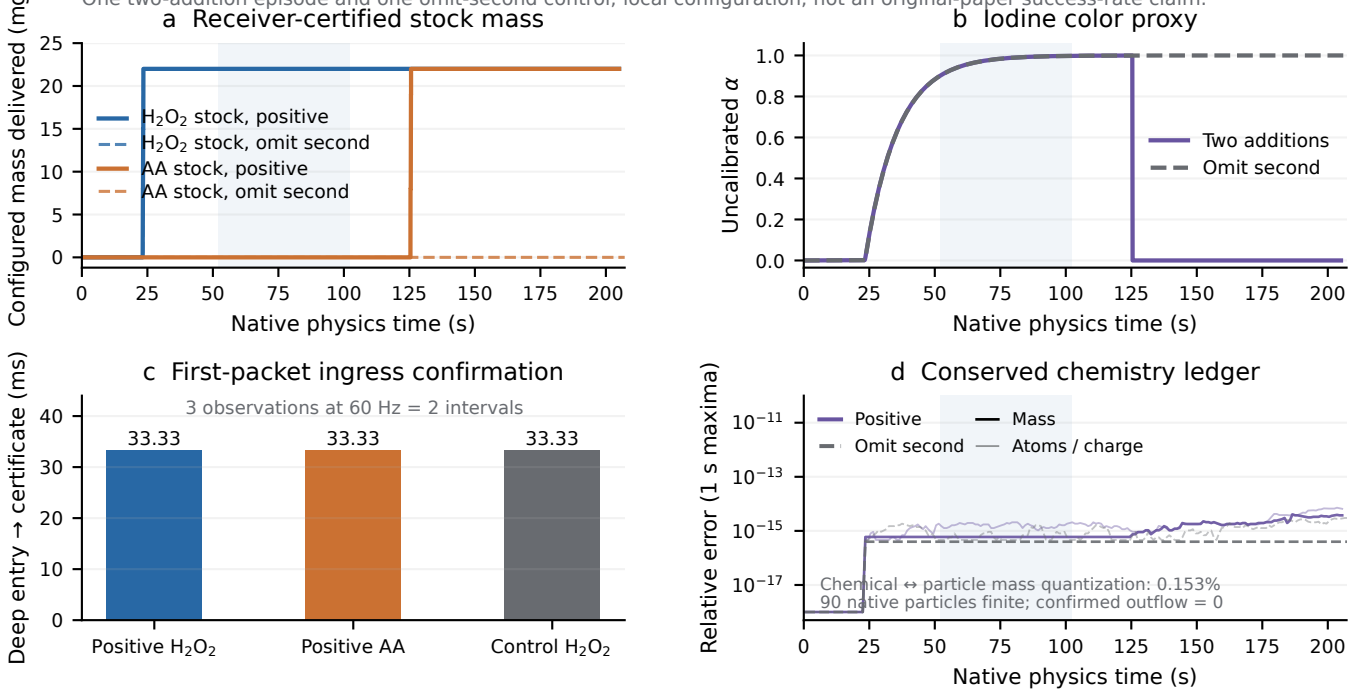
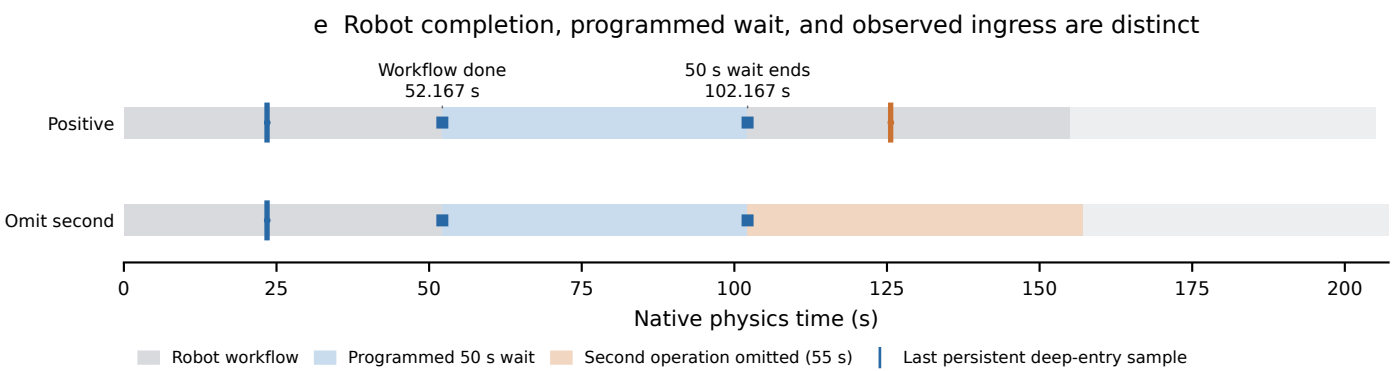
N08 · Native robot-mediated redox reconstruction

One two-addition episode and one omit-second control; local configuration, not an original-paper success-rate claim.





Observed dose gap: last persistent H_2O_2 deep-entry sample 23.450 s → first AA deep-entry sample 125.367 s = 101.917 s; sampling resolution 16.67 ms.

The 50 s interval starts after the complete first robot workflow, rather than after the last ingress. Configured particle mass is not a rendered-volume calibration.

Optical alpha is uncalibrated; finite mixing/bleaching rates and starch binding are absent. Literature oxidation k = 0.0107 L mol^{-1} s^{-1}; AA reduction uses a fast stoichiometric limit.

Methods and the public Fig. 5b CSV describe different stock recipes/roles; the printed AA concentration has a 1000× unit inconsistency. The declared Methods amounts are uniformly scaled; no kinetic fitting.
